Ignition Systems for Industrial Engines
The diesel engine (correctly known as a
compression-ignition or CI engine) is an internal combustion engine in which ignition of the fuel that has been injected into the combustion chamber is ...

What Is Compression Ignition?
Diesel Ignition System Components. Diesel engines use compression ignition instead of spark ignition, so they are
significantly different. These systems inject an air/fuel mixture into a cylinder, which is then compressed to the point where it gets so hot that it ignites without the need for a spark.

(gasoline) road vehicles such as cars and motorcycles. Compression ignition Diesel engines ignite the fuel-air mixture by the heat of compression and do not need a spark. They usually have glowplugs that preheat the combustion chamber to allow starting in cold weather. Other engines may use a flame, or a heated tube, for ignition.
Diesel engine how it work | All information about diesel engines

All conventional petrol (gasoline) engines require an ignition system. By contrast, not all engine types need an ignition system - for example, a diesel engine relies on compression-ignition, that is, the rise in temperature that accompanies the rise in pressure within the engine.
cylinder is sufficient to ignite the fuel spontaneously.

Gas turbine engines may be equipped with an electronic-type ignition system, which is a variation of the simpler capacitor-type system. The typical turbine engine is equipped with a capacitor-type, or capacitor discharge,

The diesel engine ignition system consists of two identical independent ignition units operating from a common low-voltage (DC) electrical power source: the aircraft battery, 115AC, or its permanent magnet generator.

The basic difference between a diesel engine and a gasoline engine is that in a diesel engine, the fuel
is sprayed into the combustion chambers through fuel injector nozzles just when the air in each chamber has been placed under such great pressure that it’s hot enough to ignite the fuel spontaneously. Following is a [...]

The Altronic disc-triggered digital ignition systems consist of an ignition unit, a magnetic or Hall-effect pickup, a timing disc mounted to the engine crankshaft or camshaft, wiring harnesses, and an appropriate number of ignition coils. These systems employ a cylinder position sensing design, typically using a single
Compression ignition is also commonly referred to as diesel engine, largely because it is a staple of a diesel ignition. Gasoline requires the spark ignition in order to start, but diesel can be started through this alternative means of ignition.
In a diesel engine, ignition is achieved by compression of air alone. A typical compression ratio for a diesel engine is 20:1, compared with 9:1 for a petrol engine. Compressions as great as this heat up the air to a temperature high enough to ignite the fuel spontaneously, with no need of a spark and therefore of an
ignition system.

Diesel Engine Ignition System
The diesel engine, named after Rudolf Diesel, is an internal combustion engine in which ignition of the fuel is caused by the elevated temperature of the air in the cylinder due to the mechanical compression. This contrasts with spark-
ignition engines such as a petrol engine or gas engine, which use a spark plug to ignite an air-fuel mixture. Diesel engines work by compressing only the air. This increases the air temperature inside the cylinder to such a high degree that atomised diesel fuel inj
either single or dual magneto-ignition systems. The single magneto-ignition system, usually consisting of one magneto and the necessary wiring, was used with another single magneto on the same engine.
